

Chair of Software Engineering

Einführung in die Programmierung Introduction to Programming

Prof. Dr. Bertrand Meyer

Exercise Session 7

News (Reminder)

Mock exam next week!

> Attendance is <u>highly</u> recommended (and worth one point!)

- > The week after we will discuss the results
- > Assignment 7 due on November 13

Today

\bigcirc

> Inheritance

> Genericity

Principle:

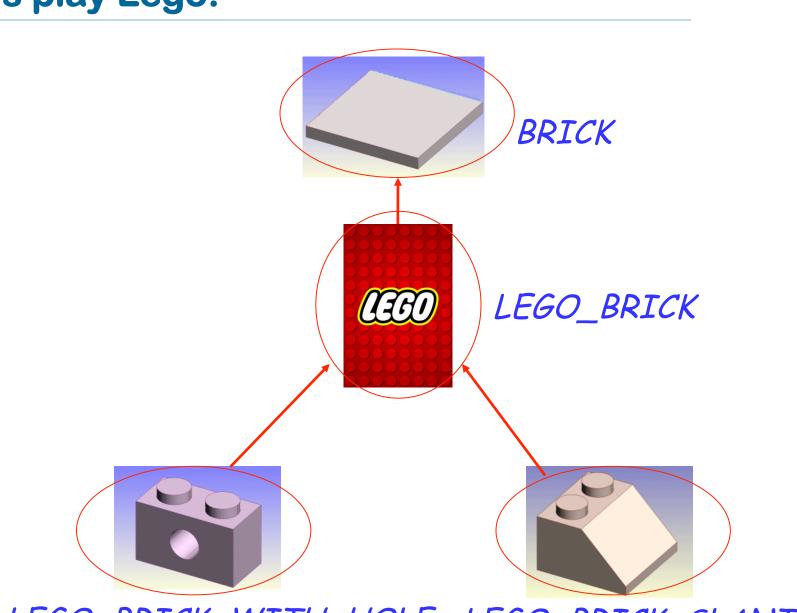

Describe a new class as extension or specialization of an existing class

(or several with *multiple* inheritance)

If *B* inherits from *A* :

- As modules: all the services of A are available in B (possibly with a different implementation)
- As types: whenever an instance of A is required, an instance of B will be acceptable ("is-a" relationship)

Let's play Lego!

LEGO_BRICK_WITH_HOLE LEGO_BRICK_SLANTED

(•)

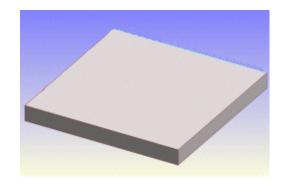

6

deferred class BRICK

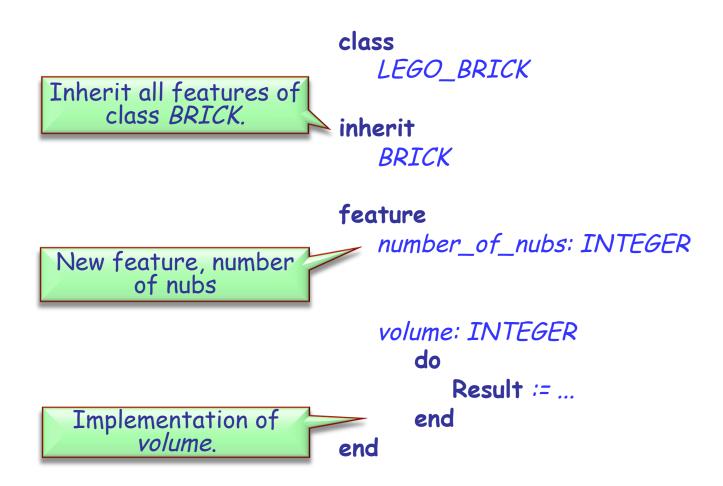

feature width: INTEGER depth: INTEGER height: INTEGER

color: COLOR

volume: INTEGER deferred end end

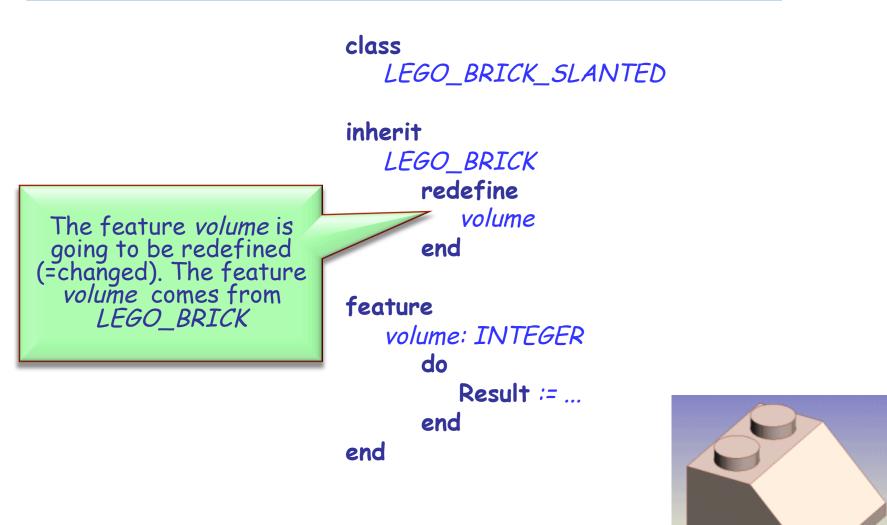

Class LEGO_BRICK

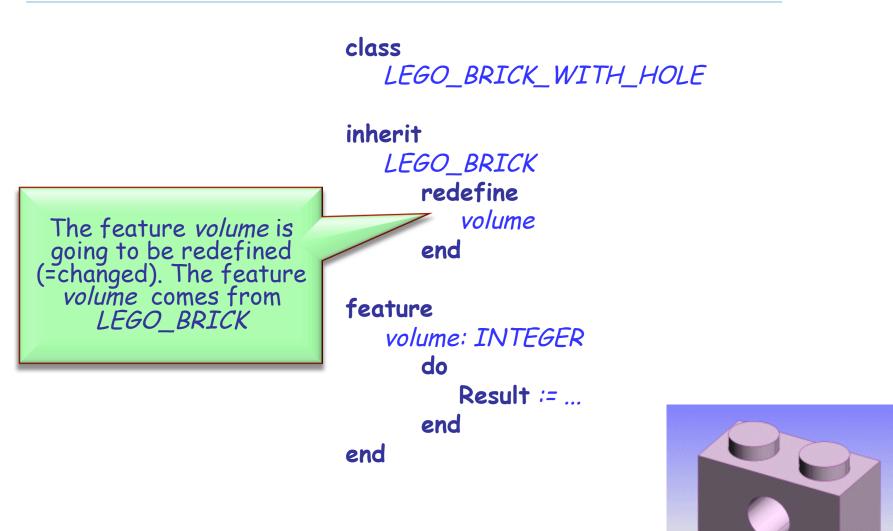

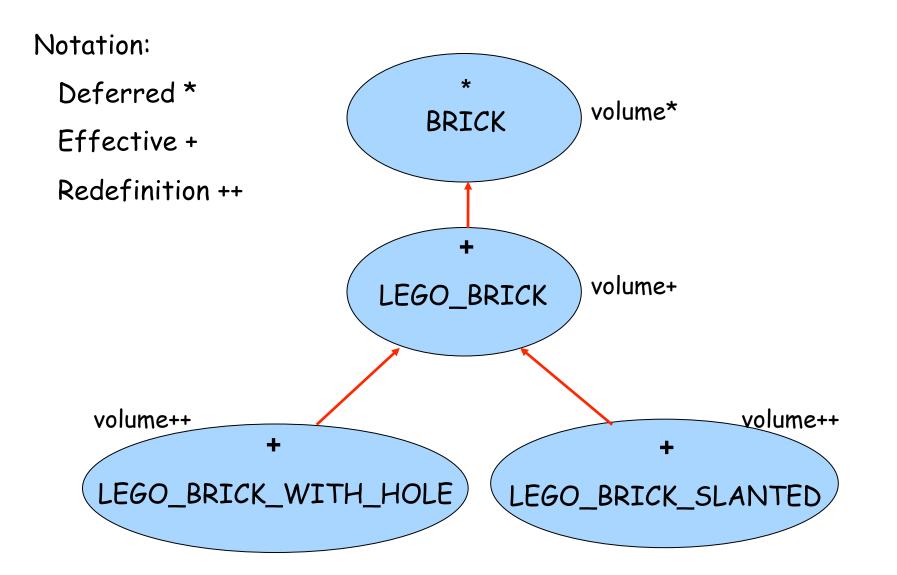

Class LEGO_BRICK_SLANTED

Class LEGO_BRICK_WITH_HOLE

Inheritance Notation

Deferred

Deferred

- Deferred classes can have deferred features.
- A class with at least one deferred feature must be declared as deferred.
- A deferred feature does not have an implementation yet.
- Deferred classes cannot be instantiated and hence cannot contain a create clause.

Can we have a deferred class with no deferred features?

Effective

\bigcirc

Effective

- Effective classes do not have deferred features (the "standard case").
- Effective routines have an implementation of their feature body.

Precursor

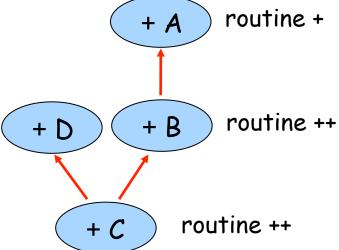

If a feature was redefined, but you still wish to call the old one, use the Precursor keyword.

```
volume: INTEGER
do
Result := Precursor - ...
end
```

A more general example of using Precursor

-- Class A routine (a_arg1 : TYPE_A): TYPE_R do ... end

-- Class C + D routine (a_arg1: TYPE_A): TYPE_R local I_loc : TYPE_R do -- pre-process $l_loc :=$ **Precursor** {B} (a_arg1) -- Not allowed: I_loc := Precursor {A} (a_arg1) -- post-process end

Today

InheritanceGenericity

Genericity - motivation

Assume we want to create a list class capable of storing objects of any type.

```
class
   LIST -- First attempt
                                    We could choose ANY
feature
                                       as the item type
   put: (a_item: ANY)
      do
         -- Add item to the list
      end
   item: ANY
      do
         -- Return the first item in the list
      end
```

-- More feature for working with the list

Working with this list – first attempt

```
insert_strings (a_list_of_strings: LIST)
   do
                                               Here we are inserting
      a_list_of_strings.put("foo")
                                                     an INTEGER
      a_list_of_strings.put(12);
      a_list_of_strings.put("foo")
   end
print_strings(a_list_of_strings: LIST)
   local
      [_printme: STRING
   do
      across a_list_of_strings as / loop
          l_printme := l.item
          io.put_string (l_printme)
      end
                                       Compile error: cannot
assign ANY to STRING
   end
```

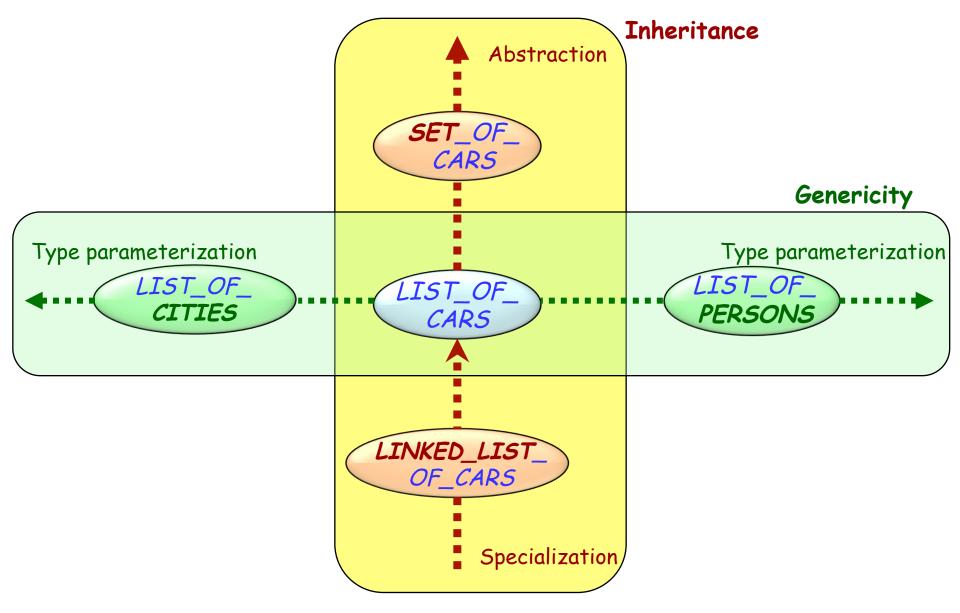

Working with this list – the right way

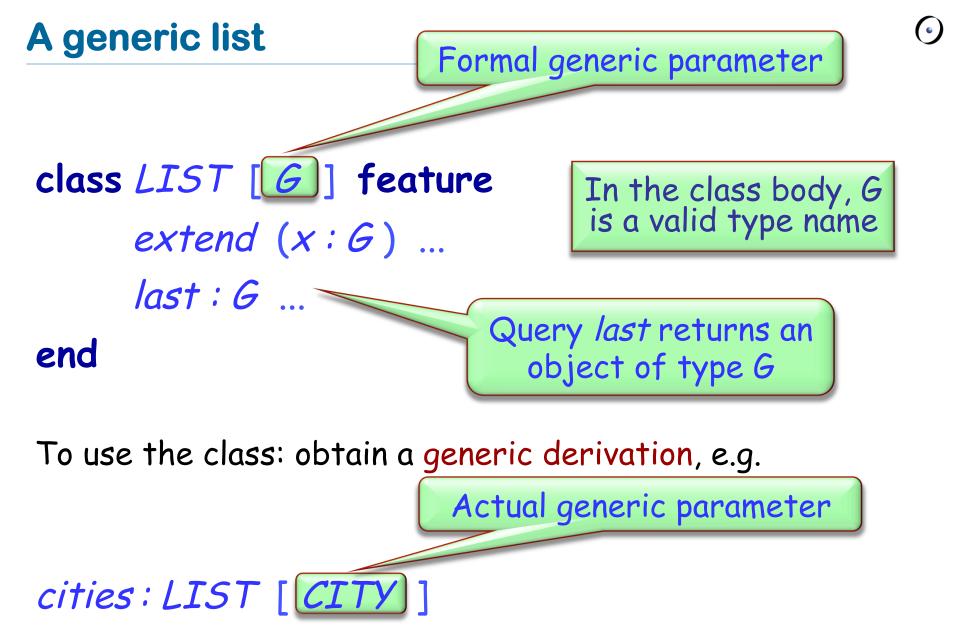

```
insert_strings (a_list_of_strings: LIST)
                                              Still nobody detects
   do
                                                   this problem
      a_list_of_strings.put("foo")
      a_list_of_strings.put(12);
                                              This solution works, but
      a_list_of_strings.put("foo")
                                            wouldn't it be nice to detect
   end
                                           this mistake at compile time?
print_strings (a_list_of_strings: LIST)
   local
                                                   Correct. This
       Lcurrent_item: ANY
                                             synctactical construct is called 'object test'.
   do
      across a_list_of_strings as / loop
          l_current_item := l.item
          if attached {STRING} |_current_item as itemstring then
             io.put_string (itemstring)
          else
             io.put_string ("The list contains a non-string item!")
          end
      end
```

Genericity

Genericity lets you parameterize a class. The parameters are types. A single class text may be reused for many different types.

class STORAGE [G]> RESOURCE inherit LIST [G]

feature consume_all do from start until after loop The feature *item* is 15 item.consume of type G. We cannot forth assume consume. end assume this. end end

Using genericity you can provide an implementation of type safe containers.

> x: ANIMAL animal_list: LINKED_LIST [ANIMAL] a_rock: MINERAL

animal_list.put (a_rock) -- Does this rock?

We use types to declare entities, as in

x: SOME_TYPE

With the mechanisms defined so far, a type is one of:

> A non-generic class e.g. METRO_STATION

A generic derivation, i.e. the name of a class followed by a list of types, the actual generic parameters, in brackets (also recursive) e.g. LIST [ARRAY [METRO_STATION]] LIST [LIST [CITY]] TABLE [STRING, INTEGER]

So, how many types can I possibly get?

Two answers, depending on what we are talking about:

Static types

Static types are the types that we use while writing Eiffel code to declare types for entities (arguments, locals, return values)

> Dynamic types

Dynamic types on the other hand are created at runtime. Whenever a new object is created, it gets assigned to be of some type.

Static types

class *EMPLOYEE* feature

> name: STRING birthday: DATE

end

class DEPARTMENT feature staff: LIST[EMPLOYEE] end

bound by the program text: *EMPLOYEE STRING DATE DEPARTMENT LIST[G] becomes LIST[EMPLOYEE]*

Object creation, static and dynamic types

```
class TEST_DYNAMIC _CREATION feature
```

ref_a: A; ref_b: B

-- Suppose B, with creation feature make_b,

-- inherits from A, with creation feature make_a

do_something do create ref_a.make_a -- Static and dynamic type is A

```
create {B} ref_a.make_b
    -- Static type is A, dynamic type is B
```

```
create ref_b.make_b
ref_a := ref_b
end
```

end

Dynamic types: another example

```
class SET[G] feature
 powerset: SET[SET[G]] is
  do
        create Result
        -- More computation...
  end
 i_th_power (i: INTEGER): SET[ANY]
  require i \ge 0
  local n: INTEGER
  do
        Result := Current
        from n := 1 until n > i loop
                 Result := Result.powerset
                 n := n + 1
        end
  end
end
```

Dynamic types from *i_th_power*: *SET[ANY] SET[SET[ANY]] SET[SET[SET[ANY]]]*

. . .
