Assignment 6: Smarties

ETH Zurich

Hand-out: 5. December 2006
Due: 12. December 2006

1 Smarter brain

Goal
In this exercise you will improve the bot brain of the estate agent in Flathunt. The estate agent’s choice of a next move when played by a bot was not really smart: He always chose the station that was farthest away from his current position. You are now going to change this!
To do

1. How does the estate agent (when played by a bot) choose his next move? This is defined in the feature `choose_next_move` of class `ESTATE_AGENT_BOT`. If you take a look at the feature you will quickly see that so far the estate agent always made the longest possible move. Look at the feature and try to understand how it is implemented.

2. Change the feature `choose_next_move` in class `ESTATE_AGENT_BOT` so that, before taking a move, the estate agent checks what the distance from the flathunters would be if he made that move. The distance is measured in number of line segments between the agent and the nearest flathunter. Of course, the larger the distance the better for the estate agent because he has a bigger chance of escaping. In the end, the agent should therefore choose the move with the largest distance. Check the hints for information on how to calculate the number of line segments between two places (plus other important features).

3. Optional: You probably realized that the new strategy, although better than the original one, still is not the smartest solution. Think about the optimal strategy of choosing the next move and implement it.

Hints

- In order to calculate the number of line segments you must add the following feature to the class `ESTATE_AGENT_BOT`.

  ```ruby
  shortest_route (a_location1, a_location2: TRAFFIC_PLACE): TRAFFIC_ROUTE is
  -- Calculate the route between two places.
  require
  a_location1_exists : a_location1 /= Void
  a_location2_exists : a_location2 /= Void
  locations_different : a_location1 /= a_location2
  local
  l: LINKED_LIST[TRAFFIC_PLACE]
  do
    create l.make
    l.extend (a_location1)
    l.extend (a_location2)
    create Result.make (l, knowledge.map)
  Result, calculate_shortest_path
  ensure
  Result_exists : Result /= Void
  end
  ```

- With the feature `knowledge.flathunter_positions` you get access to a list of the positions of all the flathunters.

- To assign the largest possible integer number to a local variable `max_int` you can use the following line of code:

  ```ruby
  max_int := feature {INTEGER}.max_value
  ```
To hand in
Submit the class text of \textit{ESTATE\_AGENT\_BOT} to your assistant. There is no need to submit logs this week.

2 Reference and expanded types, copy and twin

Goal
- Understand the difference between value and reference.
- Understand the difference between deep and shallow.

Summary

An object is made of a number of fields (attributes of the class)

A field contains either an object or a reference.

It is an object if it is an expanded type (e.g. \texttt{INTEGER}, \texttt{CHARACTER}, \texttt{DOUBLE})

It is a reference if the type is a reference type. A reference is either \texttt{Void} or attached to an object.

Example

class \texttt{BOOK}
feature
title: \texttt{STRING}
date, page_count: \texttt{INTEGER}
author: \texttt{WRITER}
end

Class \texttt{BOOK} with 4 fields, 2 of which (\texttt{STRING}, \texttt{WRITER}) are references.
Eiffel offers the following features for reference types:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x = y</code></td>
<td>compares if two references are attached to the same object</td>
</tr>
<tr>
<td><code>equal(x, y)</code></td>
<td>compares two objects (shallow comparison)</td>
</tr>
<tr>
<td><code>deep_equal(x, y)</code></td>
<td>deep comparison of objects x and y</td>
</tr>
<tr>
<td><code>x := y</code></td>
<td>attaches x to the object denoted by y (reference assignment)</td>
</tr>
<tr>
<td><code>x.copy(y)</code></td>
<td>copies the content of object y into object referenced by x (shallow copy)</td>
</tr>
<tr>
<td><code>x := y.twin</code></td>
<td>creates new object attached to x as a shallow copy of y (calls copy)</td>
</tr>
<tr>
<td><code>x := y.deep_twin</code></td>
<td>creates a new object attached to x as a deep copy of y</td>
</tr>
</tbody>
</table>

and for expanded types:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x = y</code></td>
<td>compares if two objects are the same</td>
</tr>
<tr>
<td><code>x := y</code></td>
<td>copies y into x</td>
</tr>
</tbody>
</table>

This is how the object structure before and after some commands looks like:

And here is an analogy:

Consider a HTML-page. You can compare the normal text with objects, and the links with references. Now, if you just save the web page, only the current page will be saved, the links will still point to the same pages in the WWW. However, there are some programs that allow you to make something like a deep copy, where (down to a certain level) also the referenced pages are downloaded, and the links are changed to the local copy of these references pages.
Description
This is a multiple choice exercise. First, make sure that you understood the theory above, and then try to answer questions 1 to 3.

To do
1. Suppose that the instruction $x := y$.twin has just been executed successfully, which of the following statements are true?
   (a) equal ($x$, $y$)
   (b) $x = y$
   (c) deep_equal ($x$, $y$)
2. Suppose that the instruction $x$.copy ($y$) has just been executed successfully, which of the following statements are true?
   (a) equal ($x$, $y$)
   (b) $x = y$
   (c) deep_equal ($x$, $y$)
3. Suppose that the instruction $x := y$ has just been executed, which of the following statements are true?
   (a) equal ($x$, $y$)
   (b) $x = y$
   (c) deep_equal ($x$, $y$)

To hand in
Hand in your multiple choice answers to questions 1 to 3, and the reason for your answer in question 3.

3 BNF-E in BNF-E

To do
Describe BNF-E with the help of BNF-E. Assume that the lexical constructs Keyword and Symbol (for terminals) and Identifier (for constructs) are given:

Terminal ::= Keyword | Symbol
Construct ::= Identifier

To hand in
Hand in your solution.
